Everything summarised, what happens when you click the mouse?

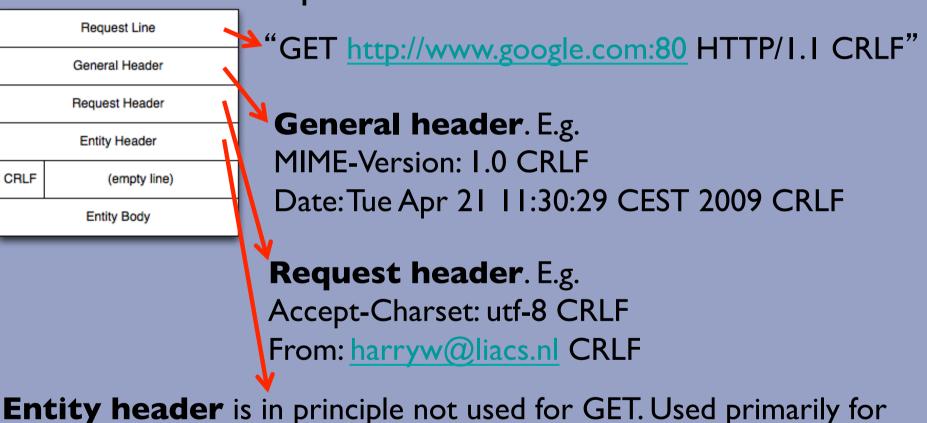

#### PC/Laptop

Leiden University. The university to discover.

click

#### Generate a HTTP packet:

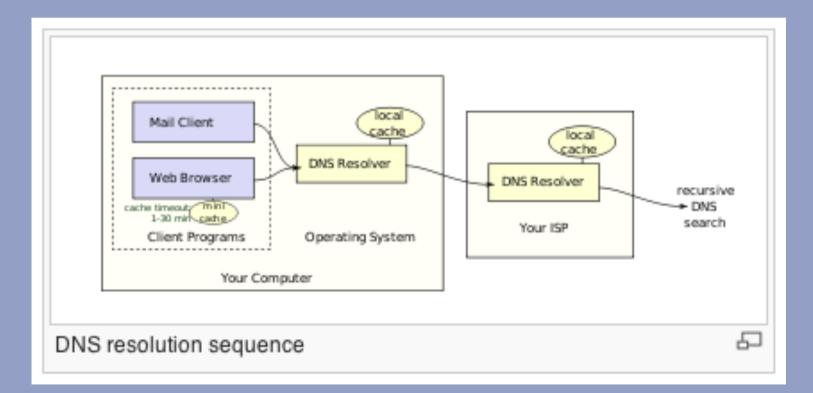

responses. E.g. Content-Encoding: gzip CRLF Title: Example CRLF

- DNS (Domain Name System) is used to lookup the IP address of the URL we are requesting.
- <u>www.google.com</u>. 173.194.67.105

#### **Domain Name System**

DNS primarily uses User Datagram Protocol (UDP) on port 53.

#### Illustration

#### https://www.youtube.com/watch?v=72snZctFFtA

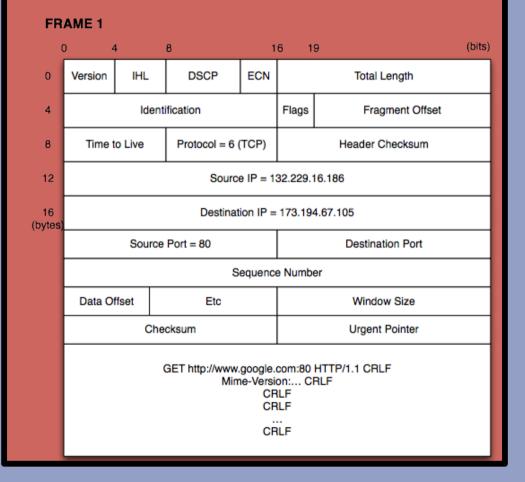

#### The Dot

The "Dot" was documented in the DNS specification, <u>RFC 1034, way</u> back in 1987.

Since a complete domain name ends with the root label, this leads to a printed form which ends in a dot. We use this property to distinguish between:

- a character string which represents a complete domain name (often called "absolute"). For example, "poneria.ISI.EDU."
- a character string that represents the starting labels of a domain name which is incomplete, and should be completed by local software using knowledge of the local domain (often called "relative"). For example, "poneria" used in the ISI.EDU domain.

 HTTP packet is embedded in a TCP/IP packet.

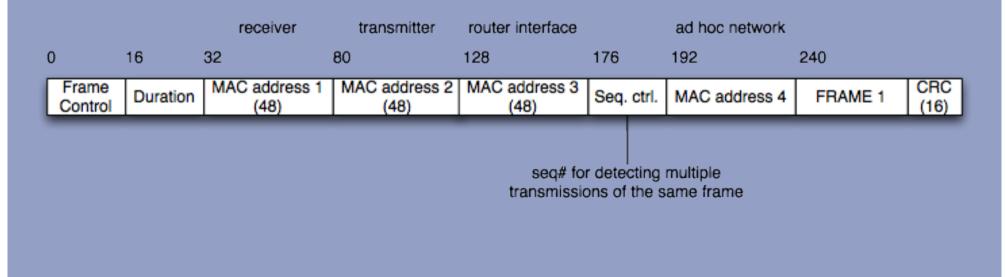

Naturally, all characters are translated using ASCII to 0 and 1

#### Scenario A

 PC/Laptop at home and connected over WiFi to a modem from a provider.

#### Step 4A

# FRAME I is embedded in a IEEE 802.11 WiFi frame.

#### Step 5A

- All the zeroes and ones are using 802.11b modulated and sent over the "ether".
- 802.11b uses Direct Sequence Spread Spectrum (DSSS) at a frequency of 2.4 GHz and a data rate of 4.3 MB/s
- Carrier sine wave is phase modulated (PM), and each I and 0 (-1) is modulated using agreed random chip sequence.

#### Step 5A

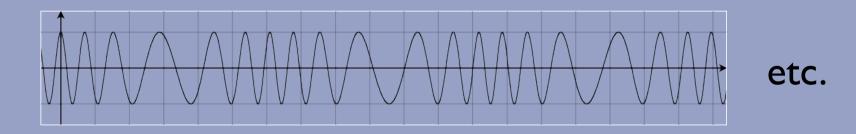

- For example, with chip sequence | | | -| | | -| -|
- I -I I is translated into:

| | | -| | | -| -| -| -| -| -| -| -| |

| | | -| | | -| -|

**Resulting Signal:** 

Note that PM and FM are more or less the same.

#### Step 6A

 WiFi receiver demodulates the received signal using the same chip sequence.

#### Step 7A

 WiFi receiver checks the sequence control field and the 16 bit CRC (Cyclic Redundancy Check) in order to verify the validity of the WiFi frame.

#### Step 8A

 Receiver takes the payload (FRAME I) out of the WiFi frame and hands the payload to the modem from the ISP.

#### Step 9A

• FRAME I is sent using the PPP protocol.

	FLAG	ADDRESS	CONTROL	PROT	OCOL	DATA	2/4 BYTES	FLAG
	01111110	11111111	00000011	0010	0001	FRAME 1	CRC	01111110
1	0x21 = IP							

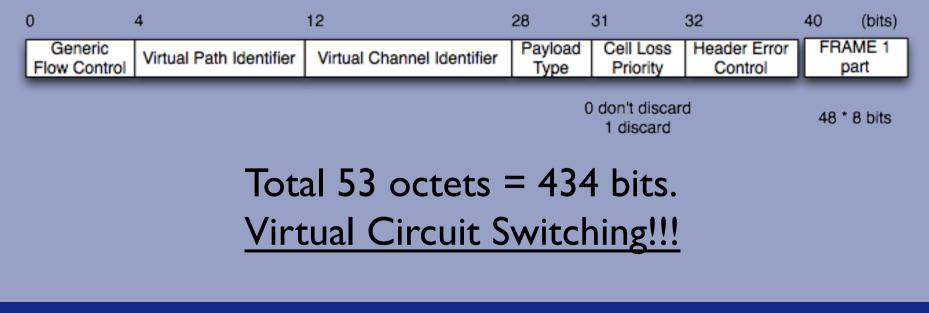

#### Step 10 A

- The PPP frame is modulated using for example 16-QAM.
- ADSL goes up to 32-QAM, but higher QAM degrees makes the signal more prone to errors.
- Signal sent using Frequency Division Multiplexing (FDM) using an upstream channel of 25-200 kHz

#### Step IIA

 The modem of the ISP demodulates the signal and does a CRC check on the received data. If OK, FRAME I will be extracted.

Assuming that the ISP has a fiber leased line to another Internet node. Then, FRAME I will be embedded in an ATM cell.

- Several ATM cells are packed in one SONET / SDH frame.
  - SONET in the US + Canada
  - SDH in EU + rest of world
- Total payload (STS-I) = 810 octets

#### Step 12A

Several communication streams from different users may be sent: <u>Time Division Multiplexing</u>

 Different light (electro magnetic radiation) modulation (PSK, ASK) in combination with wave length division multiplexing, encodes the 0 and 1 bits in a light bundle.

- Using Time Division Switching, the ATM cells are sent (through different switches) to the next router.
- Light signals are transformed into electricity and the cells are unpacked and FRAME 1 reassembled.
- Based on the source and destination address, the router looks up the next router (packet switching).
- FRAME I is again embedded in ATM cells and sent to the next router.

 If FRAME I reaches its destination it will be further routed depending on the local configuration at 173.194.67.105.

 Assuming destination is in a multi switched network, this step is similar to 4B.

- Finally, the server unpacks the TCP/IP packet and recognizes that the destination port (80) is used by the web server.
- The HTTP message is read by the web server that interprets the request line as a GET command.
- The web server generates a HTTP packet with the entity body containing the requested html page.
- HTTP response packet is sent to the source address.

#### Scenario 4B/ Step 16

 PC/Laptop at work / university and is connected to a router at work / university with fast ethernet.

IEEE 802 Media Access Protocol (MAC) + Logical Link Control (LLC).

MAC frame:

7		2/6			46-1500		
Preamble	SFD	DA	SA	type/ length	LLC data	pad	FCS

- Preamble: 10101...010
- SFD: Start Frame Delimiter: 10101011
- DA: Destination Address, MAC address of the network interface.
  - E.g. d1:21:f4:4c:31:0a, written in hexadecimal.
  - Each digit correspond to 4 bits (1 nibble).
  - Unique per interface, administrated by the IEEE.
- SA: Source Address (see DA)

- Type / length: Used by different protocols (e.g. IPX, AppleTalk) to indicate that the frame contains an LLC header.
  - Without LLC header the field contains the length of the data.
- Data
  - If the packet > 1500 B, then fragmentation
  - If the packet < 46 B, then padding</p>
- FCS/CRC: 32 bit CRC code

- How to determine the MAC addresses?
- Address Resolution Protocol (ARP)
  - Similar to DNS, but translates local network addresses to hardware addresses.
  - ARP packet with sender MAC is broadcasted with MAC address ff:ff:ff:ff:ff:ff and IP address of destination.
  - If an adapter receives the ARP packet and its IP address matches, the matching adapter will send a reply to the sender with its MAC.
  - Every host has and ARP table caching the IP, MAC for a limited time (typically 20 minutes).

#### Step 4B (IPv6)

- Neighbour Discovery Protocol (NDP)
  - Roughly the same functionality as ARP but for IPv6

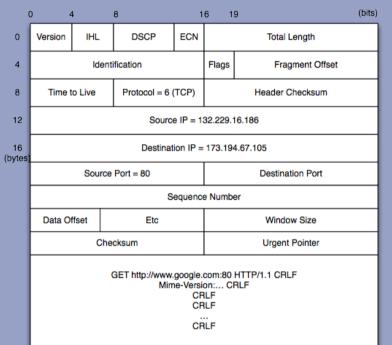

Note that Ethernet does not implement flow control. This is sufficient for IP traffic, but if flow control is needed, then MAC/LLC is used.

In the latter case, the payload will consist of:

1 B	1 B	1/2 B	
DSAP	SSAP	LLC control	Information

- DSAP (Destination Service Access Point), 8 bits, where the first bit means group or individual. Remnant of the OSI protocols.
- SSAP (Source Service Access Point), 8 bits, first bit means command or response.
- LLC control: "same" as HDLC control

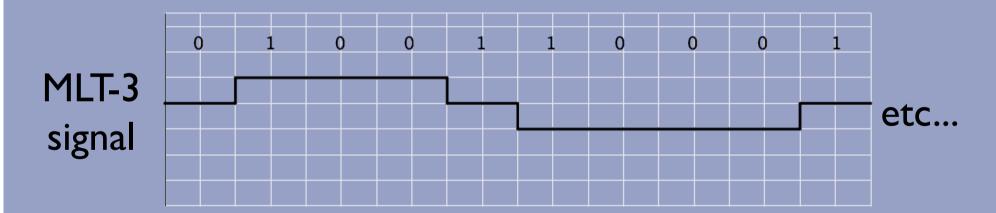

#### FRAME 1

#### FRAME I is packed in an ethernet frame:

Preamble SFD DA SA LLC/IP DSAP SSAP LLC FRAME 1 FCS

The data is sent over a twisted pair cable to the nearest switch via 100 BASETX

#### Step 5B

- The layer 2 switch looks up (using ARP) the MAC address of the next (potentially a layer 3) switch.
- The received frame is repacked with a new DA and SA.
- When the packet arrives at the router talking to the outside world, the MAC/LLC is unpacked and the packet proceeds using step 12.
